bon, was William MacGillivray, spelled with a capital G as here printed. Since the name was given in this form in the Twenty-third Supplement to the A. O. U. Checklist in the Auk for July, 1948, page 442, several friends have written me asking about this change in spelling so that it has seemed desirable to publish this note. Those who wish to look further into the matter may consult the interesting 'Life of William MacGillivray' by his namesake William MacGillivray, published in London in 1910. A plate facing page 68 in this work reproduces a hand-written letter from "W. Mac-Gillivray" to Audubon introducing Mr. Bell, under date of 19th June 1834. This signature, in the writer's own hand, is clear, so that there is no uncertainty as to the method of spelling of the name.—ALEXANDER WETMORE, Smithsonian Institution, Washington 25, D. C.

An English Sparrow Roost.—While in a hospital at Marshalltown, Iowa, October 7 to 27, 1948, I had opportunity to make observations on a roost of English Sparrows, *Passer domesticus*, in Boston ivy on the walls. No matter how bright the day, the birds began to assemble in the vines at about 4:00 p. m. and by 4:10 every day their varied chatter attracted attention. The first thought that struck me was that the struggle for existence, at least as regards the search for food, could not be very severe or the birds would not give up an hour or more of potential feeding time for the sake of the social, and presumably not so vital, attractions of the roost.

While roosts of crows, swallows, starlings, and blackbirds are formed by birds already in flocks, this assemblage was of a different type. By twos or threes, but more often as singles, the sparrows came and joined in the apparently conversational chorus, meanwhile shifting about for desirable situations. The hubbub continued until dusk, at about 5:30 on clear, or earlier on cloudy, days. In the morning the chattering came quite regularly at 6:10 a. m., and all of the birds dispersed in about half an hour. A point of interest was that, through these three weeks, absolute time, not relative degree of daylight, seemed to rule, as the beginning of both assembling and dispersing was within a 10-minute range, regardless of whether the weather was cloudy or clear. The intensity of light at the "roost-breaking" was only a fraction of that prevailing during the "roost-formation"; hence it could not have been the decisive factor in stimulating both of these activities.

There was no mass movement either to or from the roost, so this gathering did not seem to be a flock phenomenon but rather a result of coincidence in the movements of numerous individuals seeking to satisfy similar wants.—W. L. MCATEE, *Chicago*, *Illinois*.

Three Unusual Records from Louisiana and Mississippi.—On December 28, 1948, while driving on a country road about three miles east of Slaughter, East Feliciana Parish, Louisiana, I stopped my car and used the familiar "squeak" to bring up any birds in the vicinity. About three minutes after stopping, a Rosebreasted Grosbeak, *Pheucticus ludovicianus*, alighted on a blackberry briar about 15 feet away. I collected it; it proved to be a female. I am unable to find any reference to a previous winter record of the Rose-breasted Grosbeak, except a sight record reported by George H. Lowery, Jr. (Aud. Field Notes, 48th Christmas Bird Count, 1948: 100). This would, therefore, appear to be the first confirmed winter record of this species in the United States.

Howell in 'Birds of Alabama' (Alabama Dept. Game and Fisheries, 1928: 218) with reference to the Boat-tailed Grackle, *Cassidix mexicanus major*, says: "The boat-tailed grackle is a fairly common resident on the coast, but so far as known does not range into the interior." Oberholser, as well, in 'Bird Life of Louisiana' (Louisiana
